Field of the Invention

The invention relates to the fields of microbiology and molecular biology. In particular, the invention relates to the field of mycology and the production of secondary metabolites from fungi.

Summary of the Related Art

Secondary metabolites are a major source of commercially useful products such as food additives, vitamins, and medicines for the treatment of a wide variety of infections and diseases. By way of example, in 1997 the statin drugs lovastatin, simvastatin, and pravastatin, fungal secondary metabolites used in the treatment of hypercholesteremia, together had US sales of US\$7.53 billion (Sutherland et al., Current Opinion In Drug Discovery & Development 4:229-236 (2001)). and availability of these plant, bacterial and fungal metabolites are frequently determined by limitations imposed on production and purification of these compounds This problem is frequently exacerbated by from culture. the fact that these products are generally produced during the stationary phase of bacterial and fungal growth.

A wide variety of methods have been utilized to increase the amount of secondary metabolite produced in culture. Studies have demonstrated the importance of carefully designing the medium in which a fungus is grown to maximize the amount of a secondary metabolite produced (see, e.g., Hajjaj H, et al., Appl. Environ. Microbiol. 67:2596-602 (2001); Lesova, K., et al., J. Basic

40 Microbiol. 40:369-75 (2000)). In addition, the method of culture or fermentation also impacts directly on the amount of secondary metabolite produced. For example, see Robinson, T., et al. (Appl. Microbiol. Biotechnol. 55:284-

EXPRESS MAIL LABEL NO. FL 301008 763 U.S.

DATE OF DEPOSIT 10/9/01

15

20

25

30

35

5 289 (2001)), which demonstrates the advantages of solid state (substrate) fermentation.

In addition to the manipulation of culture and media conditions, genetic approaches have been taken to increase secondary metabolite production. For example, the production of penicillin is limited by the activity of two enzymes, encoded by the *ipnA* and *acvA* genes, both of which are regulated by the *pacC* protein, a zinc-finger transcription factor. Naturally occurring mutant alleles of the *pacC* locus are known to possess more transcription-activating activity than the cognate, wild-type allele (see, e.g., Tilburn et al. EMBO J. 14(4):779-790 (1995)). Thus, one genetic approach to increasing secondary metabolite production is to identify and isolate naturally occurring mutant alleles, the expression of which leads to increased secondary metabolite production.

Although many regulators of secondary metabolite production in many organisms are known, not all of the organisms that produce secondary metabolites are amenable to genetic or molecular genetic manipulation. Thus, these systems are not generally useful as a source for the isolation of naturally occurring mutant alleles and are even less useful for the deliberate manipulation of secondary metabolite regulator protein structure with the aim of creating improved regulators of secondary metabolite production.

It would be advantageous to have improved regulators of the biosynthetic enzymes responsible for secondary metabolite production. For example, recent studies suggest increasing usage of statin drugs, e.g., see Waters D.D., Am. J. Cardiol. 88:10F-5F (2001)). Thus, demand for statin drugs is likely to increase substantially. In order to meet the demand for these and other secondary metabolites, new and improved methods for the production of secondary metabolites must be identified.

BRIEF SUMMARY OF THE INVENTION

The invention provides improved secondary metabolite regulator proteins that enable increased production of secondary metabolites. The invention also provides methods to make these improved regulator proteins.

In a first aspect, the invention provides a variant regulator protein of secondary metabolite production with increased activity than that of the cognate, wild-type protein. In certain embodiments of this aspect of the invention, the regulator protein is a fungal regulator protein.

In an embodiment of the first aspect, the invention provides an improved regulator protein comprising an amino acid sequence coding for a variant lovE protein having at least one specific mutation that gives rise to greater transcription-activating properties of the regulator protein and/or induction of secondary metabolite synthesis.

By way of non-limiting example, certain preferred regulator proteins of this aspect of the invention include at least one of the following mutations: (1) a Group 6 amino acid residue mutated to a Group 2 amino acid residue at position 31, in one embodiment the mutation represented by F31L; (2) a Group 3 amino acid residue mutated to a Group 5 amino acid residue at position 41, in one embodiment the mutation represented by Q41K or Q41R; (3) a Group 4 amino acid residue mutated to a Group 2 amino acid residue at position 52, in one embodiment the mutation represented by T52I; (4) a Group 4 amino acid residue mutated to a Group 3 amino acid residue at position 52, in one embodiment the mutation represented by T52N; (5) a Group 4 amino acid residue mutated to a Group 5 amino acid residue at position 73, in one embodiment the mutation represented by C73R; (6) a Group 1 amino acid residue mutated to a Group 4 amino acid residue at position 101, in one embodiment the mutation represented by P101S; (7) a Group 1 amino acid residue mutated to a Group 3 amino acid residue at position 101, in one embodiment the mutation

represented by P101Q; (8) a valine amino acid residue 5 mutated to another Group 2 amino acid residue at position 111, in one embodiment the mutation represented by V111I; (9) a Group 4 amino acid residue mutated to a Group 2 amino acid residue at position 133, in one embodiment the 10 mutation represented by S133L; (10) a Group 3 amino acid residue mutated to a Group 2 amino acid residue at position 141, in one embodiment the mutation represented by E141V; (11) a Group 3 amino acid residue mutated to a Group 5 amino acid residue at position 141, in one 15 embodiment the mutation represented by E141K; (12) a Group 4 amino acid residue mutated to Group 6 amino acid residue at position 153, in one embodiment the mutation represented by C153Y; (13) a Group 4 amino acid residue mutated to a Group 5 amino acid residue at position 153, 20 in one embodiment the mutation represented by C153R; (14) a Group 4 amino acid residue mutated to a Group 1 amino acid residue at position 281, in one embodiment the mutation represented by T281A; (15) a Group 3 amino acid residue mutated to a Group 2 amino acid residue at position 367, in one embodiment the mutation represented 25 by N367I; (16) a Group 3 amino acid residue mutated to a Group 6 amino acid residue at position 367, in one embodiment the mutation represented by N367Y; (17) a Group 1 amino acid residue mutated to Group 4 amino acid residue 30 at position 389, in one embodiment the mutation represented by P389S; and (18) a Group 1 amino acid residue mutated to a Group 2 amino acid residue at position 389, in one embodiment the mutation represented

In some embodiments of the first aspect, the invention provides regulator proteins with at least two, or at least three, or at least four, or at least five, or at least six, or at least seven, or at least eight, or at least nine, or at least ten, or at least eleven, or at least twelve, or at least thirteen, or at least fourteen, or at least fifteen, or at least sixteen, or at least seventeen, or at least eighteen of the above described specific mutations.

by P389L.

20

25

30

35

40

In other embodiments of the first aspect, the invention provides an isolated lovE variant regulator protein selected from the group consisting of SEQ ID NO:41, SEQ ID NO:42, SEQ ID NO:43, SEQ ID NO:44, SEQ ID NO:45, SEQ ID NO:46, SEQ ID NO:47, SEQ ID NO:48, SEQ ID NO:49, SEQ ID NO:50, SEQ ID NO:51, SEQ ID NO:52, SEQ ID NO:53, SEQ ID NO:54, SEQ ID NO:55, SEQ ID NO:56, SEQ ID NO:57, SEQ ID NO:58, SEQ ID NO:59, SEQ ID NO:60, SEQ ID NO:61, SEQ ID NO:62, SEQ ID NO:63, SEQ ID NO:64, and SEQ ID NO:65.

In a second aspect, the invention provides a nucleic acid molecule encoding a lovE regulator of the first aspect of the invention. By way of non-limiting example, the invention provides a nucleic acid molecule encoding the lovE variant regulator protein selected from the group consisting of SEQ ID NO:66, SEQ ID NO:67, SEQ ID NO:68, SEQ ID NO:69, SEQ ID NO:70, SEQ ID NO:71, SEQ ID NO:72, SEQ ID NO:73, SEQ ID NO:74, SEQ ID NO:75, SEQ ID NO:76, SEQ ID NO:78, SEQ ID NO:79, SEQ ID NO:81, SEQ ID NO:82, SEQ ID NO:83, SEQ ID NO:84, SEQ ID NO:86, SEQ ID NO:87, SEQ ID NO:88, SEQ ID NO:89, and SEQ ID NO:90.

In a third aspect, the invention provides a method of increasing the activity of a protein that regulates secondary metabolite production comprising: (a) selecting a nucleic acid comprising a polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite production; and (c) selecting a variant regulator protein with more activity than the cognate, wild-type protein.

In various embodiments of the third aspect, the secondary metabolite is a fungal secondary metabolite. In certain embodiments of the third aspect, the protein regulator of secondary metabolite production is a transcription factor. In certain embodiments of the third aspect, the protein regulator of secondary metabolite production is a transmembrane transporter, protein that

30

35

40

mediates secretion, kinase, G-protein, cell surface 5 receptor, GTPase activating protein, quanine nucleotide exchange factor, phosphatase, protease, phosphodiesterase, bacterial protein toxin, importin, RNA-binding protein, SCF complex component, adherin, or protein encoded within 10 a biosynthetic cluster. In certain other embodiments of the third aspect, the variant regulator protein is selected to have more activity in a heterologous cell and/or more activity in a homologous cell than the cognate, wild-type regulator protein. In certain 15 embodiments, the variant regulator protein is selected to have more activity in a heterologous cell and/or more activity in a homologous cell than the cognate, wild-type protein and to cause more secondary metabolite to be produced in a homologous cell and/or a heterologous cell 20 when compared to the cognate, wild-type regulator protein. In a particularly preferred embodiment, the variant regulator protein is a lovE variant regulator protein.

In a fourth aspect, the invention provides a method of increasing production of a secondary metabolite comprising: (a) selecting a nucleic acid comprising a polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite production; (c) selecting a variant regulator protein with more activity than the cognate, wild-type protein; and (d) expressing the selected variant regulator protein in a cell, thereby increasing production of the secondary metabolite in the cell.

In various embodiments of the fourth aspect, the secondary metabolite is a fungal secondary metabolite. In certain embodiments of the third aspect, the protein regulator of secondary metabolite production is a transcription factor. In certain embodiments of the fourth aspect, the protein regulator of secondary metabolite production is a transmembrane transporter, a

30

35

40

protein that mediates secretion, a kinase, a G-protein, a 5 cell surface receptor, a GTPase activating protein, a quanine nucleotide exchange factor, a phosphatase, a protease, a phosphodiesterase, a bacterial protein toxin, an importin, an RNA-binding protein, an SCF complex component, an adherin, or a protein encoded within a 10 In certain other embodiments of the biosynthetic cluster. fourth aspect, the variant regulator protein is selected to have more activity in a heterologous cell and/or more activity in a homologous cell. In certain embodiments, 15 the variant regulator protein is selected to have more activity in a heterologous cell and/or more activity in a homologous cell and to cause more secondary metabolite to be produced in a homologous cell and/or a heterologous cell when compared to the cognate, wild-type regulator 20 In a particularly preferred embodiment, the variant regulator protein is a lovE variant regulator protein.

In a fifth aspect, the invention provides an isolated variant regulator protein of secondary metabolite production having increased activity compared to a cognate, wild-type protein, the variant regulator protein made by the process comprising: (a) selecting a nucleic acid comprising a polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite production; (c) selecting a variant regulator protein with more activity than the cognate, wild-type protein; and (d) recovering the selected variant regulator protein.

In certain embodiments of the fifth aspect, the secondary metabolite is a fungal secondary metabolite. In certain embodiments of the fifth aspect, the protein regulator of secondary metabolite production is a transcription factor. In certain embodiments of the fifth aspect, the protein regulator of secondary metabolite

40

production is a transmembrane transporter, a protein that 5 mediates secretion, a kinase, a G-protein, a cell surface receptor, a GTPase activating protein, a quanine nucleotide exchange factor, a phosphatase, a protease, a phosphodiesterase, a bacterial protein toxin, an importin, 10 an RNA-binding protein, an SCF complex component, an adherin, or a protein encoded within a biosynthetic .In certain embodiments of the fifth aspect, the variant regulator protein has more activity in a heterologous and/or a homologous cell than the cognate, 15 wild-type protein. In certain embodiments of the fourth aspect, the variant regulator protein increases production of a secondary metabolite in a heterologous cell and/or a homologous cell when compared to the cognate, wild-type protein. In a particularly preferred embodiment, the variant regulator protein is a lovE variant regulator 20 protein.

In a sixth aspect, the invention provides a fungus having improved lovastatin production made by the process of transforming a fungal cell with a nucleic acid molecule encoding a lovE variant protein of the first aspect of the invention. In an embodiment thereof, the nucleic acid molecule is selected from a nucleic acid molecule of the second aspect of the invention.

In a seventh aspect, the invention provides an improved process for making lovastatin comprising transforming a fungal cell with a nucleic acid molecule encoding a variant of the lovE protein of the first aspect of the invention. In an embodiment thereof, the fungal cell is transformed with a nucleic acid molecule of the second aspect of the invention.

In a eighth aspect, the invention provides a nucleic acid molecule encoding a lovE protein defined by SEQ ID NO:91. In an embodiment thereof, the invention provides an isolated *lovE* nucleic acid molecule defined by SEQ ID NO:92.

BRIEF DESCRIPTION OF THE DRAWINGS

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The patents and publications cited herein reflect the level of knowledge in the art and are hereby incorporated by reference in their entirety. Any conflict between any teaching of such references and this specification shall be resolved in favor of the latter.

The invention utilizes techniques and methods common to the fields of molecular biology, genetics and microbiology. Useful laboratory references for these types of methodologies are readily available to those skilled in the art. See, for example, Molecular Cloning, A Laboratory Manual, 3rd edition, edited by Sambrook, J., MacCallum, P., and Russell, D.W. (2001), Cold Spring Harbor Laboratory Press (ISBN: 0-879-69576-5); Current Protocols In Molecular Biology, edited by Ausubel, F.M., Brent, R., Kingston, R.E., Moore, D.D., Seidman, J.G., Struhl, K. (1993), John Wiley and Sons, Inc. (ISBN: 0-471-30661-4); PCR Applications: Protocols for Functional Genomics, edited by Innis, M.A., Gelfand, D.H., Sninsky, J.J. (1999), Cold Spring Harbor Press (ISBN: 0-123-72186-5); and Methods In Yeast Genetics, 2000 Edition: A Cold Spring Habor Laboratory Course Manual, by Burke, D., Dawson, D. and Stearns, T., Cold Spring Harbor Press (ISBN: 0-879-69588-9).

In certain embodiments of the aspects of the invention, the invention relates to the biosynthesis and improved production of secondary metabolites. The invention provides variant regulator proteins useful for the production of secondary metabolites, nucleic acid molecules encoding variant regulator proteins, and methods for their production.

In a first aspect, the invention provides a variant regulator protein of secondary metabolite production with increased activity relative to a cognate, wild-type regulator protein. Particularly preferred are variant regulator proteins of fungal secondary metabolites.

As used herein, the terms "fungal" and "fungus" refer generally to eukaryotic, heterotrophic organisms with an

- absorptive mode of nutrition. Fungi typically contain chitin in their cell walls and exhibit mycelial or yeast-like growth habits (More Gene Manipulations in Fungi, edited by J.W. Bennet and L.L. Lasure, Academic Press Inc. (1991), ISBN 0120886421). More specifically, the terms refer to secondary metabolite producing organisms including, without limitation, Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp.,
- 15 Tricotheicium sp., Fusidium sp., Emericellopsis sp.,
 Cephalosporium sp., Cochliobolus sp., Helminthosporium
 sp., Agaricus brunescens, Ustilago maydis, Neurospora sp.,
 Pestalotiopsis sp. and Phaffia rhodozyma (See, Fungal
 Physiology, Chapter 9 (Secondary(Special) Metabolism),
 20 Griffin, D. H., John Wiley & Sons, Inc.; ISBN:
 0471166154).

The term "variant regulator protein" is used herein to refer to any regulatory protein having at least one change or difference in the amino acid sequence of the protein when compared to its cognate, wild-type regulatory protein sequence. The term does not include naturally occurring allelic variations of the cognate, wild-type regulatory protein.

The term "regulator protein" is meant to refer to a

30 protein having a positive or negative function that
modifies the production of a secondary metabolite. The
function of the protein may be at the level of
transcription, e.g., repression or activation, protein
synthesis, or transport. The regulator may alter the

35 level of transcription, RNA stability, translation, posttranslational modification, or cellular localization of
proteins involved in secondary metabolite synthesis and/or
transport. The regulator may also have effects on
precursor metabolite pools, flux through specific pathways

40 and metabolite resistance.

By way of non-limiting example, certain embodiments of the aspects of the invention relate to a regulator protein that is a protein that contributes and/or promotes

25

30

35

40

transcription of a gene sequence, i.e., a transcriptionactivating protein. "Transcription-activating" is a term
used to refer to characteristics of a protein that promote
transcription. As used herein, a transcription-activating
protein would include proteins that increase accessibility
of the DNA to transcription complexes, for example, by
opening or relaxing chromatin structure, proteins that
promote the recognition and/or binding of transcription
complexes to a target gene sequence, and/or proteins that
promote transcription complex movement along the length of
the template DNA sequence.

Regulatory proteins of secondary metabolite production and the nucleic acid sequences encoding these are known to those skilled in the art. Non-limiting examples of regulatory proteins of secondary metabolite synthesis include: regulator proteins of the aflatoxin/sterigmatocystin biosynthetic cluster (Woloshuk, C.P., et al., Appl, Environ. Microbiol. 60:2408-2414 (1994) and Brown, D.W., et al., Proc Natl Acad Sci U S A. 93:1418-1422 (1996)); regulator proteins of the paxilline biosynthetic cluster (Young, C., et al., Mol, Microbiol. **39**:754-764 (2001)); regulator proteins of the cephalosporin and penicillin biosynthetic clusters (Litzka O., et al., Antonie Van Leeuwenhoek 75:95-105 (1999); Schmitt E.K. and Kuck U., J. Biol. Chem. 275:9348-9357 (2000); MacCabe et al. Mol. Gen. Genet. 250:367-374 (1996); Suarez et al. Mol. Microbiol. 20:529-540 (1996); Lambert et al. Mol. Cell. Biol. 17:3966-3976 (1997); Su et al. Genetics 133:67-77 (1993); regulator proteins of tricothecene synthesis (Trapp S.C., et al., Mol. Gen. Genet. 257:421-432 (1998); Brown D.W., et al., Fungal Genet. Biol. 32:121-133 (2001); and Matsumoto G., et al. Biosci. Biotechnol. Biochem. 63:2001-2004 (1999)); and regulator proteins of lovastatin synthesis (Kennedy, J., et al., Science 284:1368-1372 (1999); Hendrickson et al., Chem. Biol. 6:429-439 (1999) Tag, A. et al., Mol

Microbiol. 38:658-65 (2000)).

Certain embodiments of the aspects of the invention disclosed herein relate to the lovE regulator protein, a protein which plays a key role in the biosynthesis of More particularly, certain embodiments of the aspects of the invention relate to variant proteins of the lovE regulator protein and methods of making the same. 10 Such proteins are variant with respect to the following A. terreus wild-type lovE sequences (SEQ ID NOS:91 and 92).

15 As used herein, the term "secondary metabolite" means a compound, derived from primary metabolites, that is produced by an organism, is not a primary metabolite, is not ethanol or a fusel alcohol, and is not required for growth under standard conditions. Secondary metabolites

25

30

35

40

are derived from intermediates of many pathways of primary 5 metabolism. These pathways include, without limitation, pathways for biosynthesis of amino acids, the shikimic acid pathway for biosynthesis of aromatic amino acids, the polyketide biosynthetic pathway from acetyl coenzyme A 10 (CoA), the mevalonic acid pathway from acetyl CoA, and pathways for biosynthesis of polysaccharides and peptidopolysaccharides. Collectively, secondary metabolism involves all primary pathways of carbon metabolism. Particularly preferred in embodiments of the 15 aspects of the invention are fungal secondary metabolites (See, Fungal Physiology, Chapter 9 (Secondary (Special) Metabolism), Griffin, D. H., John Wiley & Sons, Inc.; ISBN: 0471166154).

"Secondary metabolite" also includes intermediate compounds in the biosynthetic pathway for a secondary metabolite that are dedicated to the pathway for synthesis of the secondary metabolite. "Dedicated to the pathway for synthesis of the secondary metabolite" means that once the intermediate is synthesized by the cell, the cell will not convert the intermediate to a primary metabolite. "Intermediate compounds" also include secondary metabolite intermediate compounds which can be converted to useful compounds by subsequent chemical conversion or subsequent biotransformation. As such, providing improved availability of such intermediate compounds would still lead to improved production of the ultimate useful compound, which itself may be referred to herein as a secondary metabolite. The yeast Saccharomyces cerevisiae is not known to produce secondary metabolites.

The term "primary metabolite" means a natural product that has an obvious role in the functioning of almost all organisms. Primary metabolites include, without limitation, compounds involved in the biosynthesis of lipids, carbohydrates, proteins, and nucleic acids. The term "increasing the yield of the secondary metabolite" means increasing the quantity of the secondary metabolite present in the total fermentation broth per unit volume of fermentation broth or culture.

As used herein, the phrase "modulate production of a 5 secondary metabolite" refers to a positive or negative or desirable change in one or more of the variables or values that affect the process or results of production of the primary or secondary metabolites in a liquid or solid state fungal fermentation. These positive or negative or 10 desirable changes include, without limitation, an increase or decrease in the amount of a primary or secondary metabolite being produced (in absolute terms or in quantity per unit volume of fermentation broth or per unit mass of solid substrate); a decrease in the volume of the 15 broth or the mass/quantity of substrate required for the production of sufficient quantities; a decrease in the cost of raw materials and energy, the time of fermentor or culture run, or the amount of waste that must be processed 20 after a fermentor run; an increase or decrease in the specific production of the desired metabolite (both in total amounts and as a fraction of all metabolites and side products made by the fungus); an increase or decrease in the percent of the produced secondary metabolite that can be recovered from the fermentation broth or culture; 25 and an increase in the resistance of an organism producing a primary or secondary metabolite to possible deleterious effects of contact with the secondary metabolite.

In certain embodiments of aspects of the invention, a 30 secondary metabolite is an anti-bacterial. An "antibacterial" is a molecule that has cytocidal or cytostatic activity against some or all bacteria. Preferred antibacterials include, without limitation, β -lactams. Preferred β -lactams include, without limitation, penicillins and cephalosporins and biosynthetic 35 intermediates thereof. Preferred penicillins and biosynthetic intermediates include, without limitation, isopenicillin N, 6-aminopenicillanic acid (6-APA), penicillin G, penicillin N, and penicillin V. Preferred 40 cephalosporins and biosynthetic intermediates include, without limitation, deacetoxycephalosporin V (DAOC V), deacetoxycephalosporin C (DAOC), deacetylcephalosporin C

15

20

25

5 (DAC), 7-aminodeacetoxycephalosporanic acid (7-ADCA), cephalosporin C, 7-B-(5-carboxy-5-oxopentanamido)-cephalosporanic acid (keto-AD-7ACA), 7-B-(4-carboxybutanamido)-cephalosporanic acid (GL-7ACA), and 7-aminocephalosporanic acid (7ACA).

In certain embodiments of aspects of the invention, the secondary metabolite is an anti-hypercholesterolemic or a biosynthetic intermediate thereof. An "anti-hypercholesterolemic" is a drug administered to a patient diagnosed with elevated cholesterol levels for the purpose of lowering the cholesterol levels. Preferred anti-hypercholesterolemics include, without limitation, lovastatin, mevastatin, simvastatin, and pravastatin.

According to other embodiments of the invention, a secondary metabolite is an immunosuppressant or a biosynthetic intermediate thereof. An "immunosuppressant" is a molecule that reduces or eliminates an immune response in a host when the host is challenged with an immunogenic molecule, including immunogenic molecules present on transplanted organs, tissues or cells.

Preferred immunosuppressants include, without limitation, members of the cyclosporin family and beauverolide L. Preferred cyclosporins include, without limitation, cyclosporin A and cyclosporin C.

In certain embodiments of aspects of the invention, 30 the secondary metabolite is an ergot alkaloid or a biosynthetic intermediate thereof. An "ergot alkaloid" is a member of a large family of alkaloid compounds that are most often produced in the sclerotia of fungi of the genus Claviceps. An "alkaloid" is a small molecule that contains nitrogen and has basic pH characteristics. 35 classes of ergot alkaloids include clavine alkaloids, lysergic acids, lysergic acid amides, and ergot peptide alkaloids. Preferred ergot alkaloids include, without limitation, ergotamine, ergosine, ergocristine, 40 ergocryptine, ergocornine, ergotaminine, ergosinine, ergocristinine, ergocryptinine, ergocorninine, ergonovine, ergometrinine, and ergoclavine.

In certain embodiments of aspects of the invention, the secondary metabolite is an inhibitor of angiogenesis or a biosynthetic intermediate thereof. An "angiogenesis inhibitor" is a molecule that decreases or prevents the formation of new blood vessels. Angiogenesis inhibitors have proven effective in the treatment of several human diseases including, without limitation, cancer, rheumatoid arthritis, and diabetic retinopathy. Preferred inhibitors of angiogenesis include, without limitation, fumagillin and ovalicin.

In certain embodiments of aspects of the invention, the secondary metabolite is a glucan synthase inhibitor or a biosynthetic intermediate thereof. A "glucan synthase inhibitor" is a molecule that decreases or inhibits the production of 1,3- β -D-glucan, a structural polymer of fungal cell walls. Glucan synthase inhibitors are a class of antifungal agents. Preferred glucan synthase inhibitors include, without limitation, echinocandin B, pneumocandin B, aculeacin A, and papulacandin.

In certain embodiments of aspects of the invention,
the secondary metabolite is a member of the gliotoxin
family of compounds or a biosynthetic intermediate
thereof. The "gliotoxin family of compounds" are related
molecules of the epipolythiodioxopiperazine class.
Gliotoxins display diverse biological activities,
including, without limitation, antimicrobial, antifungal,
antiviral, and immunomodulating activities. Preferred
members of the "gliotoxin family of compounds" include,
without limitation, gliotoxin and aspirochlorine.

In certain embodiments of aspects of the invention,
the secondary metabolite is a fungal toxin or a
biosynthetic intermediate thereof. A "fungal toxin" is a
compound that causes a pathological condition in a host,
either plant or animal. Fungal toxins could be mycotoxins
present in food products, toxins produced by
phytopathogens, toxins from poisonous mushrooms, or toxins
produced by zoopathogens. Preferred fungal toxins

include, without limitation, aflatoxins, patulin,

20

25

30

35

5 zearalenone, cytochalasin, griseofulvin, ergochrome, cercosporin, marticin, xanthocillin, coumarins, tricothecenes, fusidanes, sesterpenes, amatoxins, malformin A, phallotoxins, pentoxin, HC toxin, psilocybin, bufotenine, lysergic acid, sporodesmin, pulcheriminic acid, sordarins, fumonisins, ochratoxin A, and fusaric acid.

With some certain embodiments of aspects of the invention, the secondary metabolite is a modulator of cell surface receptor signaling or a biosynthetic intermediate thereof. The term "cell surface receptor" is as used before. Modulators of cell surface receptor signaling might function by one of several mechanisms including, without limitation, acting as agonists or antagonists, sequestering a molecule that interacts with a receptor such as a ligand, or stabilizing the interaction of a receptor and molecule with which it interacts. Preferred modulators of cell surface signaling include, without limitation, the insulin receptor agonist L-783,281 and the cholecystokinin receptor antagonist asperlicin.

In certain embodiments of aspects of the invention, the secondary metabolite is a plant growth regulator or a biosynthetic intermediate thereof. A "plant growth regulator" is a molecule that controls growth and development of a plant by affecting processes that include, without limitation, division, elongation, and differentiation of cells. Preferred plant growth regulators include, without limitation, cytokinin, auxin, gibberellin, abscisic acid, and ethylene.

In certain embodiments of aspects of the invention, the secondary metabolite is a pigment or a biosynthetic intermediate thereof. A "pigment" is a substance that imparts a characteristic color. Preferred pigments include, without limitation, melanins and carotenoids.

In certain embodiments of aspects of the invention,

40 the secondary metabolite is an insecticide or a
biosynthetic intermediate thereof. An "insecticide" is a
molecule that is toxic to insects. Preferred insecticides
include, without limitation, nodulisporic acid.

10

15

20

25

30

35

40

In certain embodiments of aspects of the invention, the secondary metabolite is an anti-neoplastic compound or a biosynthetic intermediate thereof. An "anti-neoplastic" compound is a molecule that prevents or reduces tumor formation. Preferred anti-neoplastic compounds include, without limitation, taxol (paclitaxel) and related taxoids.

The phrase "increased activity" is used herein to refer to a characteristic that results in an augmentation of the inherent negative or positive function of the regulatory protein.

The invention provides variant regulator proteins of secondary metabolite production with increased activity and methods of producing the same. The invention further provides for the identification of specific amino acid residues that are important to the functioning of secondary metabolite regulator proteins. By way of non-limiting example, variant regulator proteins of the secondary metabolite regulator lovE are presented herein.

As known to those skilled in the art, certain substitutions of one amino acid for another may be tolerated at one or more amino acid residues of a wild-type regulator protein absent a change in the structure, activity and/or function of the wild-type protein. Such substitutions are referred to in the art as "conservative" substitutions, and amino acids may be categorized into groups that identify which amino acids may be substituted for another without altering the structure and/or function of the protein.

As used herein, the term "conservative substitution" refers to the exchange of one amino acid for another in the same conservative substitution grouping in a protein sequence. Conservative amino acid substitutions are known in the art and are generally based on the relative similarity of the amino acid side-chain substituents, for example, their hydrophobicity, hydrophilicity, charge, size, and the like. In a preferred embodiment, conservative substitutions typically include substitutions within the following groups: Group 1: glycine, alanine,

20

25

30

35

40

and proline; Group 2: valine, isoleucine, leucine, and methionine; Group 3: aspartic acid, glutamic acid, asparagine, glutamine; Group 4: serine, threonine, and cysteine; Group 5: lysine, arginine, and histidine; Group 6: phenylalanine, tyrosine, and tryptophan. Each group provides a listing of amino acids that may be substituted in a protein sequence for any one of the other amino acids in that particular group.

As stated *supra*, there are several criteria used to establish groupings of amino acids for conservative substitution. For example, the importance of the hydropathic amino acid index in conferring interactive biological function on a protein is generally understood in the art (Kyte and Doolittle, *Mol. Biol.* 157:105-132 (1982). It is known that certain amino acids may be substituted for other amino acids having a similar hydropathic index or score and still retain a similar biological activity. Amino acid hydrophilicity is also used as a criteria for the establishment of conservative amino acid groupings (see, *e.g.*, U.S. Patent No. 4,554,101).

Information relating to the substitution of one amino acid for another is generally known in the art (see, e.g., Introduction to Protein Architecture: The Structural Biology of Proteins, Lesk, A.M., Oxford University Press; ISBN: 0198504748; Introduction to Protein Structure, Branden, C.-I., Tooze, J., Karolinska Institute, Stockholm, Sweden (January 15, 1999); and Protein Structure Prediction: Methods and Protocols (Methods in Molecular Biology), Webster, D.M. (Editor), August 2000, Humana Press, ISBN: 0896036375).

In one embodiment of the first aspect, the invention provides an improved regulator protein comprising an amino acid sequence coding for a variant of the lovE protein having at least one specific mutation that gives rise to greater transcription-activating properties of the regulator protein and/or increased lovastatin synthesis.

By way of non-limiting example, certain amino acid residues and mutations thereof in the lovE regulatory

25

30

35

40

protein of A. terreus (SEQ ID NO:91) are identified by the 5 invention described herein. Mutations at residues 31, 41, 52, 73, 101, 111, 133, 141, 153, 281, 367, and 389 of the wild-type lovE protein of A. terreus have been identified as being critical for the improvement of lovE regulator 10 protein function. Those mutations include: F31L, Q41K, Q41R, T52I, T52N, C73R, P101S, P101Q, V111I, S133L, E141V, E141K, C153Y, C153R, T281A, N367I, N367Y, P389S and P389L. Each mutation, therefore, represents a change of one conservative class of amino acids for another. 15 example, the mutation F31L represents a change from a Group 6 amino acid residue to a Group 2 amino acid residue at position 31 of the wild-type, lovE regulator protein.

Thus, by way of non-limiting example, regulator proteins of this aspect of the invention include at least one of the following mutations: (1) a Group 6 amino acid residue mutated to a Group 2 amino acid residue at position 31, for example, the mutation represented by F31L; (2) a Group 3 amino acid residue mutated to a Group 5 amino acid residue at position 41, for example, the mutation represented by Q41K or Q41R; (3) a Group 4 amino acid residue mutated to a Group 2 amino acid residue at position 52, for example, the mutation represented by T52I; (4) a Group 4 amino acid residue mutated to a Group 3 amino acid residue at position 52, for example, the mutation represented by T52N; (5) a Group 4 amino acid residue mutated to a Group 5 amino acid residue at position 73, for example, the mutation represented by C73R; (6) a Group 1 amino acid residue mutated to a Group 4 amino acid residue at position 101, for example, the mutation represented by P101S; (7) a Group 1 amino acid residue mutated to a Group 3 amino acid residue at position 101, for example, the mutation represented by P101Q; (8) a valine amino acid residue mutated to another Group 2 amino acid residue at position 111, for example, the mutation represented by V111I; (9) a Group 4 amino acid residue mutated to a Group 2 amino acid residue at position 133, for example, the mutation represented by S133L; (10) a Group 3 amino acid residue mutated to a

35

40

Group 2 amino acid residue at position 141, for example, 5 the mutation represented by E141V; (11) a Group 3 amino acid residue mutated to a Group 5 amino acid residue at position 141, for example, the mutation represented by E141K; (12) a Group 4 amino acid residue mutated to Group 10 6 amino acid residue at position 153, for example, the mutation represented by C153Y; (13) a Group 4 amino acid residue mutated to a Group 5 amino acid residue at position 153, for example, the mutation represented by C153R; (14) a Group 4 amino acid residue mutated to a 15 Group 1 amino acid residue at position 281, for example, the mutation represented by T281A; (15) a Group 3 amino acid residue mutated to a Group 2 amino acid residue at position 367, for example, the mutation represented by N367I; (16) a Group 3 amino acid residue mutated to a Group 6 amino acid residue at position 367, for example, 20 the mutation represented by N367Y; (17) a Group 1 amino acid residue mutated to Group 4 amino acid residue at position 389, for example, the mutation represented by P389S; and/or (18) a Group 1 amino acid residue mutated to a Group 2 amino acid residue at position 389, for example, 25

In other embodiments of the first aspect, the invention provides a variant of the lovE regulator protein with at least two, or at least three, or at least four, or at least five, or at least six, or at least seven, or at least eight, or at least nine, or at least ten, or at least eleven, or at least twelve, or at least thirteen, or at least fourteen, or at least fifteen, or at least sixteen, or at least seventeen, or at least eighteen of the above described specific mutations.

the mutation represented by P389L.

In other embodiments of the first aspect, the invention provides an isolated lovE variant regulator protein having the sequence of SEQ ID NO:41, SEQ ID NO:42, SEQ ID NO:43, SEQ ID NO:44, SEQ ID NO:45, SEQ ID NO:46, SEQ ID NO:47, SEQ ID NO:48, SEQ ID NO:49, SEQ ID NO:50, SEQ ID NO:51, SEQ ID NO:52, SEQ ID NO:53, SEQ ID NO:54, SEQ ID NO:55, SEQ ID NO:56, SEQ ID NO:57, SEQ ID NO:58,

15

30

35

40

5 SEQ ID NO:59, SEQ ID NO:60, SEQ ID NO:61, SEQ ID NO:62, SEQ ID NO:63, SEQ ID NO:64, or SEQ ID NO:65.

In a second aspect, the invention provides a nucleic acid molecule encoding a variant regulator protein of secondary metabolite production of the first aspect of the invention. As used herein, the terms "nucleic acid" or "nucleic acid molecule" refer to a deoxyribonucleotide or ribonucleotide polymer in either single-or double-stranded form, and unless otherwise limited, would encompass analogs of natural nucleotides that can function in a similar manner as the naturally occurring nucleotide.

In one embodiment of the second aspect, the invention provides a nucleic acid molecule encoding a variant protein of the lovE regulator protein of the first aspect of the invention.

By way of non-limiting example, the invention provides a nucleic acid molecule encoding a lovE variant regulator protein having the sequence of SEQ ID NO:66, SEQ ID NO:67, SEQ ID NO:68, SEQ ID NO:69, SEQ ID NO:70, SEQ ID NO:71, SEQ ID NO:72, SEQ ID NO:73, SEQ ID NO:74, SEQ ID NO:75, SEQ ID NO:76, SEQ ID NO:78, SEQ ID NO:79, SEQ ID NO:81, SEQ ID NO:82, SEQ ID NO:83, SEQ ID NO:84, SEQ ID NO:86, SEQ ID NO:87, SEQ ID NO:88, SEQ ID NO:89, or SEQ ID NO:90.

Poor transformation efficiency and the lack of efficient selection systems frequently precludes the screening of large numbers of variant regulator proteins of secondary metabolites in the organism from which the regulator protein is isolated. For example, there are currently certain technical obstacles to the successful screening of large numbers of variant regulator proteins in the fungus A. terreus, an organism that produces the secondary metabolite lovastatin.

The invention described herein takes advantage of the genetically tractable and experimentally amenable organism Saccharomyces cerevisiae for screening large numbers of variant regulator proteins of secondary metabolite production. Techniques common to the field of molecular biology are well developed in S. cerevisiae, and large

25

30

35

40

numbers of vectors are available to assist the genetic manipulation and cloning of variant regulator proteins involved in secondary metabolite production. Other genetically tractable organisms could also be used for this purpose.

In a third aspect, the invention provides a method of increasing the activity of a protein that regulates secondary metabolite production comprising: (a) selecting a nucleic acid comprising a polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite production; and (c) selecting a variant regulator protein with more activity than the cognate, wild-type protein.

As used herein, "mutating" is used to refer to the deliberate alteration of at least one nucleotide residue of a wild-type, cognate nucleic acid sequence encoding a regulator protein of secondary metabolite production. A deliberate alteration or change in at least one nucleotide residue of a polynucleotide may be accomplished by any method known in the art. The mutation(s) can be made in vivo or in vitro and can include random, partially random or not random, i.e., directed, mutagenesis techniques.

By way of non-limiting example, in vivo mutagenesis can be done by placing this nucleic acid molecule in a cell with a high mutation frequency, i.e. a mutagenic strain. By way of non-limiting example, Muhlrad et al. (Yeast 8:79-82 (1992)) have developed a rapid method for localized mutagenesis of yeast genes. As a first step, the region of interest of a gene sequence is first amplified in vitro under error-prone polymerase chain reaction (PCR) conditions. Error-prone polymerase chain reaction (PCR) is a method of introducing amino acid changes into proteins. With this technique, mutations are deliberately introduced during the PCR reaction through the use of error-prone DNA polymerases under specific reaction conditions. With the Muhlrad et al. procedure, the PCR product is then co-transformed with a gapped

15

20

25

35

40

plasmid containing homology to both ends of the PCR 5 product, resulting in in vivo recombination to repair the gap with the mutagenized DNA.

There are a variety of commercially available kits that may be used to produce mutant nucleic acid molecules by error-prone PCR (see, e.q., GeneMorph™ PCR Mutagenesis Kit (Stratagene, La Jolla, California); and Diversify™ PCR Random Mutagenesis Kit (BD Biosciences Clontech, Palo Alto, CA). Thus, a plurality of variant, i.e., mutated, regulator proteins of secondary metabolite production may be produced using established mutagenesis techniques.

As used herein, the term "activity" refers to a characteristic of the regulator protein that negatively or positively affects the biological system to bring about a modulation in secondary metabolite production. By way of non-limiting example, the activity is the transcription of downstream genes involved in the biosynthetic pathway of the secondary metabolite of choice. Thus, in the present example, the phrase "more activity" refers to the property of a variant regulator protein to bring about more transcription than that effected by the cognate, wild-type regulator protein.

In certain embodiments of the third aspect, the selected variant regulator protein has more activity in a fungal cell than the cognate, wild-type protein. certain embodiments of the third aspect, the protein 30 regulator of secondary metabolite production is a transcription factor. In certain embodiments of the fourth aspect, the protein regulator of secondary metabolite production is a transmembrane transporter, a protein that mediates secretion, a kinase, a G-protein, a cell surface receptor, a GTPase activating protein, a guanine nucleotide exchange factor, a phosphatase, a protease, a phosphodiesterase, a bacterial protein toxin, an importin, an RNA-binding protein, an SCF complex component, an adherin, or a protein encoded within a biosynthetic cluster. . In certain other embodiments of the third

aspect, the selected variant regulator protein has more 5 activity in a heterologous cell than the cognate, wildtype protein. In certain embodiments thereof, the heterologous cell is an organism selected from the group consisting of S. cerevisiae, E. coli, A. nidulans, Candida sp., and N. crassa. In yet certain other embodiments of 10 the third aspect, the selected variant regulator protein has more activity in a homologous cell than the cognate, wild-type protein. In certain embodiments thereof, the homologous cell is an organism selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium 15 chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp., Tricotheicium sp., Fusidium sp., Emericellopsis sp., Cephalosporium sp., Cochliobolus sp., Helminthosporium sp., Agaricus brunescens, Ustilago 20

maydis, Neurospora sp., Pestalotiopsis sp., and Phaffia

In certain embodiments of the third aspect, the selected variant regulator protein has more activity in a 25 heterologous cell and a homologous cell than the cognate, wild-type protein. In certain embodiments thereof, the heterologous cell is an organism selected from the group consisting of S. cerevisiae, E. coli, A. nidulans, Candida sp., and N. crassa and the homologous cell is an organism 30 selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp., Tricotheicium sp., Fusidium sp., Emericellopsis sp., Cephalosporium sp., Cochliobolus sp., Helminthosporium 35 sp., Agaricus brunescens, Ustilago maydis, Neurospora sp., Pestalotiopsis sp. and Phaffia rhodozyma.

As used herein, the phrase "heterologous cell" refers to a system for gene expression, *i.e.*, an organism for gene expression, that is one other than the organism from which the selected regulator protein of secondary

rhodozyma.

metabolite production has been isolated. Preferred 5 heterologous cells include, but are not limited to, S. cerevisiae, E. coli, A. nidulans, and Candida sp., and N. Particularly preferred are fungal heterologous In an embodiment of the third aspect, the method cells. comprises: (a) selecting a nucleic acid comprising a 10 polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite 15 production; and (c) selecting a mutagenized nucleic acid encoding a variant regulator protein with increased activity in a homologous cell than the cognate, wild-type protein.

As used herein, the phrase "homologous cell" refers to a system for gene expression, i.e., an organism for gene expression, that is the organism from which the regulator protein of secondary metabolite production has been isolated. Preferred homologous cells are fungal homologous cells, including, but not limited to,

- 25 Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp., Tricotheicium sp., Fusidium sp., Emericellopsis sp., Cephalosporium sp., Cochliobolus sp.,
- 30 Helminthosporium sp., Agaricus brunescens, Ustilago maydis, Neurospora sp., Pestalotiopsis sp and Phaffia rhodozyma. (See, Fungal Physiology, Chapter 9 (Secondary(Special) Metabolism), Griffin, D. H., John Wiley & Sons, Inc.; ISBN: 0471166154).

In certain embodiments of the third aspect, the method further comprises selecting a variant regulator protein that also increases production of a secondary metabolite in a cell when compared to the cognate, wild-type protein. In certain embodiments thereof, the cell is a fungal cell. In certain embodiments thereof, the cell is a heterologous cell, preferably selected from the group

15

20

25

30

35

40

5 consisting of S. cerevisiae, E. coli, A. nidulans, Candida sp., and N. crassa.

In certain embodiments thereof, the cell is a homologous cell, preferably selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp., Tricotheicium sp., Fusidium sp., Emericellopsis sp., Cephalosporium sp., Cochliobolus sp., Helminthosporium sp., Agaricus brunescens, Ustilago maydis, Neurospora sp., Pestalotiopsis sp., and Phaffia rhodozyma.

Certain embodiments of the aspects of the invention relate to regulator proteins that promote secondary metabolite production by increasing transcription of one or more genes involved with secondary metabolite production. These wild-type sequences may be selected for mutagenesis to create a plurality of variant regulator proteins. The activity of these transcription-activating variant regulator proteins may be determined by measuring the activity of a reporter gene having the appropriate promoter sequences. These tests are done in a homologous and/or a heterologous cell. Certain embodiments of aspects of the invention are directed to fungal regulator proteins with transcription-activating activity that is tested in fungal heterologous and homologous cells.

Reporter genes are useful for isolating transformants expressing improved variant regulator proteins. The reporter genes may be operably linked to a promoter sequence that is normally regulated by the wild-type regulator protein. Reporter genes include, but are not limited to, genes encoding β -galactosidase (lacz), β -glucoronidase (GUS), β -glucosidase, amylase and invertase, amino acid biosynthetic genes, e.g., the yeast LEU2, HIS3, LYS2, TRP1 genes (or homologous genes from other fungi, such as filamentous fungi, that encode proteins with the similar functional activities), nucleic acid biosynthetic

30

35

genes, e.g., the yeast URA3 and ADE2 genes (or homologous 5 genes from other fungi, such as filamentous fungi, that encode proteins with the similar functional activities), the mammalian chloramphenicol transacetylase (CAT) gene, or any surface antigen gene for which specific antibodies 10 are available. A reporter gene can also be a neomycin phosphotransferase(neo) gene, which encodes neomycin, kanamycin resistance gene and G418 (geneticin) resistance A reporter gene may encode a protein detectable by luminescence or fluorescence, such as green fluorescent 15 protein (GFP). Reporter genes may additionally or alternatively encode any protein that provides a phenotypic marker, for example, a protein that is necessary for cell growth or viability, or a toxic protein that causes cell death. Alternatively, the reporter gene 20 may encode a protein detectable by a color assay leading to the presence or absence of color.

The choice of reporter gene will depend on the type of cell to be transformed. Preferred reporter genes are those that are operable in fungal cells. It is preferable to have two reporter genes within the cell. One reporter gene, when expressed, provides a growth advantage to transformed cells that are expressing the variant regulator protein. This allows for the isolation of such transformants though selective pressures. The other reporter gene provides a colorimetric marker, such as the lacZ gene and its encoded protein, β -galactosidase. Alternatively, the second reporter provides a fluorescent or luminescent marker, such as green fluorescent protein (GFP).

In a fourth aspect, the invention provides a method of increasing production of a secondary metabolite comprising: (a) selecting a nucleic acid comprising a polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to 40 create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite production; (c) selecting a variant regulator protein with 5 more activity than the cognate, wild-type protein; and (d) expressing the selected variant regulator protein in a cell, thereby increasing production of the secondary metabolite in the cell.

In certain embodiments of the fourth aspect, the cell 10 is a fungal cell. In certain embodiments of the fourth aspect, the protein regulator of secondary metabolite production is a transcription factor. In certain embodiments of the fourth aspect, the protein regulator of secondary metabolite production is a transmembrane 15 transporter, a protein that mediates secretion, a kinase, a G-protein, a cell surface receptor, a GTPase activating protein, a guanine nucleotide exchange factor, a phosphatase, a protease, a phosphodiesterase, a bacterial protein toxin, an importin, an RNA-binding protein, an SCF 20 complex component, an adherin, or a protein encoded within a biosynthetic cluster. In certain embodiments of the fourth aspect, the cell is a heterologous cell, preferably selected from the group consisting of S. cerevisiae, E. coli, A. nidulans, Candida sp., and N. crassa. In certain other embodiments of the fourth aspect, the cell is a 25 homologous cell, preferably selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma 30 sp., Tolypocladium sp., Tricotheicium sp., Fusidium sp., Emericellopsis sp., Cephalosporium sp., Cochliobolus sp., Helminthosporium sp., Agaricus brunescens, Ustilago maydis, Neurospora sp., Pestalotiopsis sp., and Phaffia

In certain other embodiments of the fourth aspect, the cell is a heterologous cell and the method further comprises expressing the variant regulator protein in a homologous cell, thereby increasing secondary metabolite production in the homologous cell. In certain embodiments thereof, the heterologous cell is an organism selected from the group consisting of *S. cerevisiae*, *E. coli*, *A*.

rhodozyma.

- 5 nidulans, Candida sp., , and N. crassa and the homologous cell is an organism selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp.,
- 10 Tolypocladium sp., Tricotheicium sp., Fusidium sp.,
 Emericellopsis sp., Cephalosporium sp., Cochliobolus sp.,
 Helminthosporium sp., Agaricus brunescens, Ustilago
 maydis, Neurospora sp., Pestalotiopsis sp.and Phaffia
 rhodozyma.

In a fifth aspect, the invention provides an isolated variant regulator protein of secondary metabolite production having increased activity compared to a cognate, wild-type protein, made by the process comprising: (a) selecting a nucleic acid comprising a polynucleotide encoding a protein regulator of secondary metabolite production; (b) mutating the nucleic acid to create a plurality of nucleic acid molecules encoding variant regulator proteins of secondary metabolite production; (c) selecting a variant regulator protein with more activity than the cognate, wild-type protein; and (d) recovering the selected variant regulator protein.

In certain embodiments of the fifth aspect, the variant regulator protein selected has more activity in a fungal cell. In certain embodiments of the fifth aspect, 30 the protein regulator of secondary metabolite production is a transcription factor. In certain embodiments of the fifth aspect, the protein regulator of secondary metabolite production is a transmembrane transporter, a protein that mediates secretion, a kinase, a G-protein, a cell surface receptor, a GTPase activating protein, a 35 guanine nucleotide exchange factor, a phosphatase, a protease, a phosphodiesterase, a bacterial protein toxin, an importin, an RNA-binding protein, an SCF complex component, an adherin, or a protein encoded within a 40 biosynthetic cluster. In certain embodiments of the fifth aspect, the variant regulator protein selected has

- from the group consisting of S. cerevisiae, E. coli, A. nidulans, Candida sp., Neurospora sp., Pestalotiopsis sp., and N. crassa. In certain embodiments of the fifth aspect, the variant regulator protein selected has more activity in a homologous cell, preferably selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp., Tricotheicium sp.,
- 15 Fusidium sp., Emericellopsis sp., Cephalosporium sp., Cochliobolus sp., Helminthosporium sp., Agaricus brunescens, Ustilago maydis, Neurospora sp., Pestalotiopsis sp., and Phaffia rhodozyma.

In certain embodiments of the fifth aspect, the
variant regulator protein selected has more activity in a
homologous cell and a heterologous cell. In embodiments
thereof, the heterologous cell is an organism selected
from the group consisting of S. cerevisiae, E. coli, A.
nidulans, Candida sp., Neurospora sp., Pestalotiopsis sp.,

- and N. crassa and the homologous cell is an organism selected from the group consisting of Aspergillus sp., Penicillium sp., Acremonium chrysogenum, Yarrowia lipolytica, Nodulisporium sp., Fusarium sp., Monascus sp., Claviceps sp., Trichoderma sp., Tolypocladium sp.,
- 30 Tricotheicium sp., Fusidium sp., Emericellopsis sp.,
 Cephalosporium sp., Cochliobolus sp., Helminthosporium
 sp., Agaricus brunescens, Ustilago maydis, Neurospora sp.,
 Pestalotiopsis sp., and Phaffia rhodozyma.

In yet another embodiment of the fifth aspect, the
variant regulator protein is a variant protein of the lovE
protein having at least one of the following mutations:
(1) a Group 6 amino acid residue mutated to a Group 2
amino acid residue at position 31, for example, the
mutation represented by F31L;(2) a Group 3 amino acid
residue mutated to a Group 5 amino acid residue at
position 41, for example, the mutation represented by Q41K

or Q41R; (3) a Group 4 amino acid residue mutated to a 5 Group 2 amino acid residue at position 52, for example, the mutation represented by T52I; (4) a Group 4 amino acid residue mutated to a Group 3 amino acid residue at position 52, for example, the mutation represented by 10 T52N; (5) a Group 4 amino acid residue mutated to a Group 5 amino acid residue at position 73, for example, the mutation represented by C73R; (6) a Group 1 amino acid residue mutated to a Group 4 amino acid residue at position 101, for example, the mutation represented by 15 P101S; (7) a Group 1 amino acid residue mutated to a Group 3 amino acid residue at position 101, for example, the mutation represented by P101Q; (8) a valine amino acid residue mutated to another Group 2 amino acid residue at position 111, for example, the mutation represented by 20 V111I; (9) a Group 4 amino acid residue mutated to a Group 2 amino acid residue at position 133, for example, the mutation represented by S133L; (10) a Group 3 amino acid residue mutated to a Group 2 amino acid residue at position 141, for example, the mutation represented by 25 E141V; (11) a Group 3 amino acid residue mutated to a Group 5 amino acid residue at position 141, for example, the mutation represented by E141K; (12) a Group 4 amino acid residue mutated to Group 6 amino acid residue at position 153, for example, the mutation represented by C153Y; (13) a Group 4 amino acid residue mutated to a 30 Group 5 amino acid residue at position 153, for example, the mutation represented by C153R; (14) a Group 4 amino acid residue mutated to a Group 1 amino acid residue at position 281, for example, the mutation represented by 35 T281A; (15) a Group 3 amino acid residue mutated to a Group 2 amino acid residue at position 367, for example, the mutation represented by N367I; (16) a Group 3 amino acid residue mutated to a Group 6 amino acid residue at position 367, for example, the mutation represented by 40 N367Y; (17) a Group 1 amino acid residue mutated to Group 4 amino acid residue at position 389, for example, the mutation represented by P389S; and/or (18) a Group 1 amino

acid residue mutated to a Group 2 amino acid residue at

35

40

position 389, for example, the mutation represented by P389L.

In certain embodiments of this aspect of the invention, the variant protein of the lovE protein sequence has an amino acid sequence of SEQ ID NO:41, SEQ ID NO:42, SEQ ID NO:43, SEQ ID NO:44, SEQ ID NO:45, SEQ ID NO:46, SEQ ID NO:47, SEQ ID NO:48, SEQ ID NO:49, SEQ ID NO:50, SEQ ID NO:51, SEQ ID NO:52, SEQ ID NO:53, SEQ ID NO:54, SEQ ID NO:55, SEQ ID NO:56, SEQ ID NO:57, SEQ ID NO:58, SEQ ID NO:59, SEQ ID NO:60, SEQ ID NO:61, SEQ ID NO:62, SEQ ID NO:63, SEQ ID NO:64, or SEQ ID NO:65.

In another embodiment thereof, the variant protein of the lovE protein is encoded by a nucleic acid molecule having a polynucleotide sequence of SEQ ID NO:66, SEQ ID NO:67, SEQ ID NO:68, SEQ ID NO:69, SEQ ID NO:70, SEQ ID NO:71, SEQ ID NO:72, SEQ ID NO:73, SEQ ID NO:74, SEQ ID NO:75, SEQ ID NO:76, SEQ ID NO:78, SEQ ID NO:79, SEQ ID NO:81, SEQ ID NO:82, SEQ ID NO:83, SEQ ID NO:84, SEQ ID NO:86, SEQ ID NO:87, SEQ ID NO:88, SEQ ID NO:89, or SEQ ID NO:90.

In a sixth aspect, the invention provides a fungus having improved lovastatin production made by the process of transforming a fungal cell with a nucleic acid molecule encoding a variant of the lovE protein of the first aspect of the invention. In an embodiment thereof, the nucleic acid molecule is selected from a nucleic acid molecule of the second aspect of the invention.

In a seventh aspect, the invention provides an improved process for making lovastatin comprising transforming a fungal cell with a nucleic acid molecule encoding a variant of the lovE protein of the first aspect of the invention. In an embodiment thereof, the fungal cell is transformed with a nucleic acid molecule of the second aspect of the invention.

International Patent Application PCT/US99/29583 discloses lovastatin production genes. However, this reference does not provide a mature *lovE* cDNA sequence. The invention herein remedies the shortcoming of this

15

25

30

35

5 reference by providing a complete cDNA sequence for the lovE mRNA.

In an eighth aspect, the invention provides a nucleic acid molecule encoding a lovE protein defined by SEQ ID NO:91. In an embodiment thereof, the invention provides an isolated *lovE* nucleic acid molecule defined by SEQ ID NO:92.

The following examples illustrate the preferred modes of making and practicing the present invention but are not meant to limit the scope of the invention since alternative methods may be utilized to obtain similar results.

EXAMPLES

20 Example 1: Preparation of Strains and Plasmids

Strain MY2124 was derived from the Sigma 1278b strain background of S. cerevisiae and its complete genotype is as follows: $MAT\alpha/MAT\alpha$::LEU2 ura $3\Delta0$ /ura $3\Delta0$ leu $2\Delta0$ /leu $2\Delta0$ 0 trp1 $\Delta0$:: $hisG/trp1\Delta0$::hisG his $3\Delta0$:: $hisG/his3\Delta0$::hisG ura $3\Delta0$::lovF-HIS3p-neo/ura $3\Delta0$. MY2124 can be constructed by mating S. cerevisiae strains MY2112 ($MAT\alpha$ ura $3\Delta0$ leu $2\Delta0$ trp1 $\Delta0$::hisG his $3\Delta0$::hisG ura $3\Delta0$::lovFp-HIS3p-neo) with MY1555 ($mat\alpha$::LEU2 ura $3\Delta0$ leu $2\Delta0$ trp1 $\Delta0$::hisG and isolating zygotes. The ura $3\Delta0$::lovFp-HIS3p-neo allele of MY2112 was derived by cotransforming SfiI-linearized plasmid MB2254 with pRS424 (Sikorski and Hieter (1989) Genetics 122:19-27) into MY1413 ($MAT\alpha$ leu $2\Delta0$ trp1 $\Delta0$::hisG his $3\Delta0$::hisG). Transformants were

selected on SC-Trp media and subsequently screened for 5-fluoro-orotic acid resistance to identify those transformants containing the ura3\Delta0::lovFp-HIS3p-neo allele. Trp segregants lacking plasmid pRS424 were isolated by growing the strain under non-selective conditions.

The following oligonucleotides were used in the construction of plasmids.

Plasmid MB2254 contains the lovFp-HIS3p-neo reporter gene flanked by URA3 sequence. First primers MO664 (SEQ ID NO:1) and MO665 (SEQ ID NO:2) were annealed and inserted into the KpnI-SacI sites of plasmid pBluescript II KS (Stratagene,). The resulting vector, MB1038, contains a SalI site in the polylinker. Next, the SpeI-XhoI fragment from pJL164 (Brachmann et al. Yeast 14:115-132 (1998)) containing a deletion of the URA3 gene with additional flanking sequences was inserted into the NheI-SalI sites of MB1038 to create MB1053. Primers MO666 (SEQ ID NO:3) and MO667 (SEQ ID NO:4) that contain multiple restriction sites (NotI, XbaI, SpeI, XhoI and KpnI) were then annealed together and ligated into the SmaI site of MB1053 to create MB1054. Next, the following four fragments were combined in MB1054 to obtain plasmid The lovF promoter from A. terreus genomic DNA was PCR amplified with MO1794 (SEQ ID NO:5) and MO1793 (SEQ ID NO:6) and inserted into MB1054 on a NotI-SpeI fragment. The HIS3 basal promoter from pRS403 (Sikorski and Hieter, Genetics 122:19-27 (1989)) was PCR amplified with primers MO1785 (SEQ ID NO:7) and MO1786 (SEQ ID NO:8) and inserted into MB1054 on a SpeI-BamHI fragment. Finally, the neo gene (PCR amplified with MO195 (BamHI) (SEQ ID NO:) and MO196 (EcoRI) (SEQ ID NO:10) from plasmid pYX11 (Xiao and Weaver, Nucl. Acids Res. 25:2985-2991 (1997)) and CYC1 terminator sequences (XhoI-KpnI fragment from pRS426-GAL-S (Mumberg, et al., Nucl. Acids. Res. 22:5767-5768 (1994)) were first combined in pRS416 (Sikorski and Hieter,

15

20

25

30

35

5 Genetics 122:19-27 (1989)) and then cut out with BamHI-KpnI and inserted into MB1054 to create MB2254.

The lovFp-HIS3p-neo reporter in MY2124 can confer resistance to the drug geneticin (G418). empirically determined that MY2124 (untransformed or transformed with parental plasmids MB2478 (CYC1-lovE/CEN) or MB2848 (CYC1-lovE/At274/CEN) was unable to grow on YPD media supplemented with 100 μg /ml G418. Plasmid MB2478 contains the CYC1 promoter operationally linked to the entire A. terreus lovE open reading frame. The CYC1 promoter is a relatively weak promoter and thus the lovE ORF in MB2478 was expressed at low levels. MB2478 was the parental vector plasmid for creating full length lovE variants. Plasmid MB2848 contains the CYC1 promoter operationally linked to a chimeric open reading frame consisting of the A. terreus lovE DNA binding domain fused to the carboxy-terminal portion of the At274 gene (U.S. Serial No. 60/257,431, filed December 22, 2000).

MB2848 was used to create *lovE* variants in which the DNA binding domain was not mutated. Both MB2478 and MB2848 contain yeast CEN and autonomously replicating sequences and both are maintained at 1-2 copies per cell. In contrast to strains transformed with MB2478 or MB2848, strains transformed with plasmid MB1644 (*TEF1-lovE/2* micron) were able to grow on G418-supplemented YPD media. The *lovE* gene of MB1644 is under control of the

constitutively strong *S. cerevisiae TEF1* promoter. MB1644 contains a 2-micron origin for high-copy replication in yeast. An objective of these studies was to identify *lovE* variants which when expressed at low levels could confer G418 resistance similar to the highly expressed wild-type *lovE* molecule of MB1644. *S. cerevisiae* expression vectors used in these studies were constructed as follows.

MB968 is a low copy *S. cerevisiae URA3* based expression vector. MB968 was created by inserting the 40 *Eco*RV fragment (containing the destination cassette) from gateway pEZC7201 (Invitrogen™, Carlsbad, CA) into

40

10

5 XhoI/SalI (filled in with Klenow) linearized pRS416 CYC1 (Mumberg, et al., Gene 156:119-122 (1995)).

MB1644 and MB2478 are URA3-based S. cerevisiae
expression plasmids that contain the wild-type lovE gene.
They are both derivatives of MB1199. MB1199 was created
by using primers MO841 (SEQ ID NO:11) and MO842 (SEQ ID
NO:12) to amplify the lovE ORF from A. terreus cDNA.
Gateway (Invitrogen™, Carlsbad, CA) Cloning Technology (US
Patent 5,888,732) was used to clone the lovE PCR fragment
into the gateway entry vector pDONR206 (Invitrogen™,
Carlsbad, CA) to create MB1199. Similarly, Gateway

Carlsbad, CA) to create MB1199. Similarly, Gateway Cloning Technology was used to transfer the *lovE* ORF from MB1199 into MB968 to create MB2478 and into MB969 (U.S. Serial No. 60/198,335, filed April 18, 2000) to create MB1644.

MB2848 is a derivative of MB968 that contains a loveAT274 chimera. The love portion of MB2848 was derived by
using oligos MO841 (SEQ ID NO:11) and MO2278 (SEQ ID
NO:13) to PCR amplify the love DNA binding domain from A.
terreus cDNA. A second round of PCR was performed with
primers MO343 (SEQ ID NO:14) and MO2278 to add appropriate
Gateway Cloning Technology compatible sequences. The
At274 portion of MB2848 can be derived by using primers
MO2273 (SEQ ID NO:15) and MO2274 (SEQ ID NO:16) to PCR
amplify the carboxy-terminal domain of At274 from A.

terreus cDNA. A second round of PCR was performed with

primers MO344 (SEQ ID NO:17) and MO2273 to add appropriate Gateway Cloning Technology compatible sequences. The *lovE* and *At274* PCR products were cut with *Bam*HI and purified over a QIAquick PCR purification kit (Qiagen, Valencia, CA) according to manufacturer's instructions. Finally, the products were mixed 3-4 hours in a standard ligation

reaction and used in Gateway entry and destination reactions to create MB2848.

Gateway cloning technology was used to clone the lovE variants of interest into plasmid MB1419 which is a filamentous fungal expression vector. The MB1419 fungal selection marker is the *A. nidulans GPD* promoter controlling the *ble* gene from *S. hindustanus*. The

25

30

5

transgene is controlled by the A. nidulans PGK promoter.

A. terreus strain MF117 is a derivative of A. terreus strain ATCC 20542.

Example 2: PCR Mutagenesis of the love DNA Binding Domain

The zinc finger DNA binding domain of love is encoded by nucleotides 100-201 (SEQ ID NO:92). Oligos MO2624 (SEQ ID NO:18) and MO2654 (SEQ ID NO:19) were used to PCR amplify a love containing fragment from plasmid MB2478. The 1.7 kb product contains nucleotides 212-1410 of love and ~500 bp of flanking vector sequence. Two rounds of standard PCR (1.5 mM MgCl₂) were performed with Amplitaq DNA polymerase (Applied Biosystems, Foster City, Ca) according to the manufacturer's instructions.

Plasmid MB2848 was cut with *KpnI-BamHI* to release a 1.1 kb fragment containing the *At274* portion of the *lovE-At274* chimeric open reading frame. The remaining 5.5 kb vector sequence retains the *lovE* DNA binding domain.

Example 3: PCR Mutagenesis of the lovE Open Reading Frame
 lovE open reading frame insert was prepared according
to the following procedure. Oligo pairs MO2680 (SEQ ID
NO:20) /MO2686 (SEQ ID NO:21), MO2681 (SEQ ID NO:22)
/MO2686, and MO2700 (SEQ ID NO:23) /MO2701 (SEQ ID NO:24)
were used to PCR amplify the entire lovE open reading
frame from plasmid MB2478. The PCR products differ in the
amount of 5' and 3' vector sequence flanking the lovE open

PCR was performed using a GeneMorph PCR mutagenesis kit (Stratagene, La Jolla, Ca) according to manufacturer's instructions to achieve medium and high range mutation frequencies.

Plasmid MB2478 was cut with Asp718/XbaI to release a 1.7 kb fragment. The remaining 5.0 kb vector sequence completely lacks lovE ORF sequence.

Example 4: Transformation and Selection for G418R Isolates

40

35

reading frame.

- All PCR products were purified using a QIAquick PCR purification kit (Qiagen) according to manufacturer's instructions. All vectors were gel purified using a QIAquick gel extraction kit (Qiagen) according to manufacturer's instructions.
- The mutagenesis strategy of Muhlrad et al. (Yeast 8:79-82 (1992)) was used which involves cotransforming a mutated PCR product and gapped plasmids into S. cerevisiae, and then screening for in vivo recombinants having the desired phenotype).
- Transformation of Saccharomyces cerevisiae was accomplished by the lithium acetate/single-stranded carrier DNA/polyethylene glycol (LiAc/ss-DNA/PEG) protocol (Woods R.A. and Gietz R.D. Methods Mol. Biol. 177:85-97 (2001)) with a 1:5 molar ratio of vector:insert DNA to generate >55,000 in vivo recombinant transformants on SC-Ura plates. Transformants were transferred by replica printing to YPD plates containing 100 μg/ml G418 and allowed to grow for 2-4 days at 30°C (Figure 1).

Drug resistant clones were confirmed in secondary
assays including growth on G418 concentrations up to 2000
μg/ml. The plasmid-dependence of the phenotype was
determined by observing the re-appearance of drug
sensitivity correlating with loss of the library plasmid.
lovE variant plasmids were recovered from promising
candidates (Hoffman and Winston (1986) Gene 57:267). More
than 70 lovE variants were identified and definitively
characterized by DNA sequence and/or restriction digestion
analysis.

Table 3 summarizes the G418 resistance phenotype and sequence analysis of 26 of these variants.

Example 5: Increased lovF-lacZ Expression in S. cerevisiae

In order to quantify the increase in lovF expression,
β-galactosidase activity was measured in lovE variant
transformed S. cerevisiae strains that also harbored
lovFp-lacZ reporter derivative plasmids. lovF-lacZ
reporter derivative plasmids were constructed as follows.

Plasmid MB1918 contains the lovFp-lacZ reporter gene. It can be derived from pRS424 (Sikorski and Hieter (1989) Genetics 122:19-27). First, primers MO107 (SEQ ID NO:25) and MO197 (SEQ ID NO:26) are used to PCR amplify the lacZ gene from Yep355 (Myers, et al., Gene 45:299-310 (1986)). This lacZ-containing fragment was inserted into the BamHI-HindIII sites of pRS416 (Sikorski and Hieter, Genetics 122:19-27 (1989)). This same lacZ fragment can be cut out of the resulting vector with KpnI-NotI and inserted into the same sites of pRS424 to create pRS424-lacZ. Primers MO1293 (SEQ ID NO:27) and MO1294 (SEQ ID NO:28) are used

10

15

20

25

to PCR amplify a 2.09 kb fragment of the lovF promoter from A. terreus genomic DNA. The lovF promoter fragment was then cut with NotI-BglII and inserted into NotI-BamHI linearized pRS424-lacZ.

Plasmid MB2114 contains the <code>lovFp-CYC1p-lacZ</code> reporter gene. It can be derived from pRS424-lacZ (see MB1918 plasmid construction). Primers MO1787 (SEQ ID NO:29) and MO1788 (SEQ ID NO:30) are used to amplify the 264 bp basal <code>CYC1</code> element from pRS415 CYC1 (Mumberg, <code>et al.</code>, <code>Gene 156:119-122 (1995))</code>. This 264 bp fragment was inserted upstream of the pRS424-lacZ derivative which has been digested with <code>SpeI-BamHI</code>. Finally, the <code>lovF</code> promoter from MB1918 was PCR amplified with MO1793 (SEQ ID NO:31) and MO1794 (SEQ ID NO:32) and inserted into the <code>NotI-SpeI</code> sites to create MB2114.

Yeast strains utilized in this study include strains MY2145 and MY2159, which are both derived from the S. cerevisiae sigma 1278b strain background; the genotypes are both strains are as follows: MATa $ura3\Delta0$ $leu2\Delta0$ $his3\Delta::hisG$ $trp1\Delta0::hisG$. MY2145 and MY2159 contain the lovFp-lacZ reporter plasmids MB2114 and MB1918, respectively.

MY2124 transformed with individual lovE variant plasmids was mated to S. cerevisiae strains MY2154 and MY2159. Diploids were selected on SC-UraTrp media. 30 Multiple diploids from each individual mating were assayed for lovFp-lacZ expression using 96 well format β galactosidase assays. For β -galactosidase assays, cells were transferred from transformation plates to 96-well microtiter plates containing 200 μ l Z buffer. 12 strains 35 were transferred simultaneously using a 12-channel multipipettor to scoop cells from transformation plates. Duplicate samples were prepared for all assays. OD600 readings were taken on samples in Z buffer. These values were used to normalize for equal cell number in all 40 assays. After determining OD_{600} , 150 μl of each sample in

35

Z buffer was transferred onto a Millipore Multiscreen Assay System (Nitrocellulose Immobilon NC), filtered, and then washed by filtering 200 μ l Z buffer. 100 μ l Z buffer with β ME and detergents was then added to each well, as was 20 μ l 4 mg/ml ONPG. Reactions were incubated at 30°C,

stopped with 50µl 1 M Na_2CO_3 , filtered into a polystyrene 96-well assay plate, and OD_{420} was determined for each assay well. β -galactosidase units were determined using the Miller formula (O.D. 420 X 1000)/

(OD600*minutes*volume in mL). Z buffer is made by

dissolving the following in 1 L of water (16.1 g Na₂HPO₄7H₂O, 5.5g NaH₂PO₄-H₂O, 0.75 g KCl and 0.246 g MgSO₄-7H₂O).

Z buffer with detergents and βME is made as follows: 9.8
ml Z buffer, 100 μl 20 mg/ml CTAB, 100 μl 10 mg/ml sodium
deoxycholate, and 69 μl βME Control plasmids utilized in

these studies included MB968, MB2478 and MB1644.

Results of these studies are presented in Figures 2-5, demonstrating increased transcription-activating properties of the *lovE* variants disclosed herein.

25 Example 6: Secondary Metabolite Production

Transformation of filamentous fungi was performed according to the following procedure. Protoplasts were generated by inoculating rich media with spores. Spores were allowed to germinate for about 20 hrs or until germ tubes were between 5 and 10 spore lengths. The germlings were centrifuged and washed twice with sterile distilled water and once with 1 M magnesium sulfate. Germlings were then resuspended in 1M magnesium sulfate containing approximately 2 mg/ml of Novozyme. Tubes were then incubated at 30°C shaking at 80 RPM for about 2 hrs or until most of the hyphae were digested and protoplasts were abundant. Protoplasts were filtered through one layer of Miracloth. At least one volume of STC was added and protoplasts were centrifuged. Protoplasts were washed

15

20

25

5 twice with STC. Protoplasts then were resuspended in 1ml STC and counted in a hemacytometer. A final concentration of approximately 5 x 10⁷ protoplasts/ml were frozen in a 9:1:0.1 solution of STC, SPTC and DMSO in a Nalgene Cryo cooler at -80°C (cools -1°C/min).

Solutions for transformation were as follows: STC (0.8 M Sorbitol, 25 mM Tris-HCl pH 7.5, 25 mM CaCl,) and SPTC (0.8 M Sorbitol, 40% PEG 4000, 25 mM Tris-HCl pH 8, 50 mM CaCl,). Transformation was accomplished according to the following protocol. 1-5 μg of DNA comprising a lovE variant according to the invention in a fungal expression vector was placed in a 50 ml Falcon tube. 100 μ l of previously frozen protoplasts were added to the DNA, gently mixed, and then incubated on ice for 30 min. 15 μl of SPTC was added, followed by mixing by tapping and incubation at RT for 15 min. 500 μ l SPTC was added and mixed well by tapping and rolling, then incubated at RT for 15 min. 25 mls of regeneration minimal medium was added, mixed well and poured on plates containing 25 mls of regeneration minimal medium with 2X the concentration of selection drug.

Transformation plates were incubated at 26°C for 5-6 days or until colonies started to appear. Regeneration minimal medium contains trace elements, salts, 25 mM sodium nitrate, 0.8 M Sucrose, and 1% agarose at pH 6.5.

- The selection drug that was used successfully with A.

 terreus is phleomycin, a broad-spectrum glycopeptide
 antibiotic. Transformants were picked onto new plates
 with a toothpick (if the fungus was sporulating) or with
 sterile forceps (if the fungus did not sporulate).
- Purification plates contained minimal medium (same as regeneration minimal medium but containing 2 % instead of 0.8 M sucrose) and 1X drug concentration. Picked transformants were incubated at 26°C for 5-6 days.

Transformants were grown in production media for 40 secondary metabolite production. Briefly, for A. terreus and lovastatin production, spores were used as the inoculum. Spores were obtained from the purification

- plate by using a wooden inoculation stick. The medium was RPM containing corn steep liquor, sodium nitrate, potassium phosphate, magnesium sulfate, sodium chloride, P2000 (Dow chemical), trace elements and lactose or glucose as carbon source. The medium was pH 6.5. Flasks were incubated at 26°C with shaking at 225 RPM. For static 96-well cultures, the same medium was used and the spores were obtained from the purification plate with a wooden toothpick. 96-well plates were incubated, without shaking at 26°C.
- 15 Sampling was done after after 5 days for lovastatin. For shake flask experiments 1-1.5 mls of supernatant was placed into 96-well plates, which were centrifuged and supernatants transferred to new 96-well plates. Samples were frozen at 80°C for storage or for later assays.

Cultures that were grown standing in a 96-well plate were centrifuged and the supernatant was transferred to a new 96 well plate. Samples were frozen at 80°C.

25 Example 7: Measurement of Secondary Metabolite Production

The concentration of the secondary metabolite lovastatin was determined by enzyme inhibition assay (Figure 6). Briefly, 10 μL of sample was removed and diluted 1:100 in H_2O . 10 μl of this diluted broth was assayed in a reaction (200 μL total) containing 1 mM HMGCoA, 1 mM NADPH, 0.005 mM DTT and 5 μl (His) HMGR. The disappearance of absorbance at 340 nm was observed over time. This represents the disappearance of NADPH, and lovastatin inhibits this reaction.

35 The initial velocities were calculated for the reactions containing samples, adjusted for dilution, and compared to reactions containing lovastatin standards to determine levels of metabolite produced. (His), HMGR was expressed in Saccharomyces cerevisiae and purified with a 10 nickel column.

The results from ten individual transformants for each allele are shown in standard box plot format in

20

25

30

35

40

5 Figure 6. Lovastatin concentration from the corresponding wild-type lovE control is shown in matching fill pattern. For example, lovE alleles 2, 7, 8 and 9 were all transformed and assayed at the same time as the non-hatched wild-type control. The horizontal line in each individual box represents the median.

Lovastatin concentration was also determined by high pressure liquid chromatography (HPLC). Briefly, 100 µL of broth sample was removed and diluted 1:10 into 70% H₂O-30% acetonitrile (900 µl). This mixture was spun down to pellet debris at 13000 RPM for 5 minutes. 900 µl of this diluted broth was transferred to a vial and the sample was analyzed by HPLC. 10 µl were injected into a Waters HPLC system (996 photo-diode array detector, 600 E pump controller and 717 autosampler) equipped with a YMC-Pack ODS column (Aq-302-3, 150 x 4.6 mm ID, S-3 µM pore size) and eluted with isocratic 40% aqueous acetic acid (0.7%)-60% acetonitrile for 8 minutes. Lovastatin was detected at 238 nm to have a retention time of 6.5 minutes and was quantified using a calibration curve created from pure lovastatin samples.

The results from ten individual transformants for each *lovE* variant are shown in standard box plot format in Figure 7A and 7B. Thirty individual wild-type *lovE* transformants and ten individual MB2143 negative control transformants were tested. Identical controls are plotted in Figures 7A and 7B.

PCR analysis of A. terreus transformants demonstrates that greater than fifty percent of the transformants contain the transgene. Variability in levels of transgene expression can presumably be influenced by integration site and copy number. lovE variants containing identical amino acid substitutions are labeled.

The amino acid and nucleic acid sequences of *lovE* variant sequences are presented in Table 5 and Table 6, respectively.

Table 5: Amino Acid Sequences of Variants of the lovE Gene

Equivalents

Those skilled in the art will recognize, or be able to ascertain, using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are intended to be encompassed by the following claims.
